Adsorption kinetics, isotherms and thermodynamic studies

Pseudo-first-order and pseudo-second-order kinetic models were usually used to describe the relationship between adsorption rate and substrate concentration. The kinetics equations were shown as follows:

$$\ln\left(1 - \frac{q_t}{q_e}\right) = -k_1 \times t \quad (1)$$

$$\frac{t}{q_t} = \frac{1}{k_2 q_e^2} + \frac{t}{q_e} \quad (2)$$

where q_e denotes the equilibrium adsorption capacity ($\text{mg}\cdot\text{g}^{-1}$), q_t is the adsorption capacity ($\text{mg}\cdot\text{g}^{-1}$) at a certain time; k_1 (min^{-1}) and k_2 ($\text{g}\cdot(\text{mg}\cdot\text{min})^{-1}$) are the rate constants.

The Langmuir model considers that the monolayer adsorption occurs on the uniform surface of the adsorbent. The equation is expressed as follows:

$$\frac{C_e}{q_e} = \frac{1}{c_L q_{\max}} + \frac{C_e}{q_m} \quad (3)$$

where C_e ($\text{mg}\cdot\text{L}^{-1}$) and q_e ($\text{mg}\cdot\text{g}^{-1}$) represents the equilibrium adsorption concentration and equilibrium adsorption capacity, respectively; q_{\max} ($\text{mg}\cdot\text{g}^{-1}$) represents the maximum adsorption capacity and c_L ($\text{L}\cdot\text{mg}^{-1}$) is the Langmuir constant.

The Freundlich adsorption model considers adsorption to occur on the nonuniform surface and is calculated by the following Eqs. :

$$\log q_e = \log c_F + \frac{\log C_e}{n} \quad (4)$$

where C_e ($\text{mg}\cdot\text{L}^{-1}$) and q_e ($\text{mg}\cdot\text{g}^{-1}$) denotes the equilibrium concentration and the equilibrium adsorption capacity at a certain solution concentration, respectively; Freundlich constant c_F ($\text{L}\cdot\text{mg}^{-1}$) and $1/n$ can be obtained from the linear plot of $\log q_e$ versus $\log C_e$.

The change thermodynamic values of enthalpy (ΔH , $\text{kJ}\cdot\text{mol}^{-1}$), Gibbs free energy (ΔG , $\text{kJ}\cdot\text{mol}^{-1}$) and entropy (ΔS , $\text{J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$) were represented as follows:

$$K_C = \frac{q_e}{C_e} \quad (5)$$

$$\Delta G = - RT \ln K_C \quad (6)$$

$$\Delta G = \Delta H - T\Delta S \quad (7)$$

where T (K) is the temperature, K_c is the equilibrium constant and R ($8.314 \text{ J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$) is the ideal gas constant. q_e ($\text{mg}\cdot\text{g}^{-1}$) and C_e ($\text{mg}\cdot\text{L}^{-1}$) are the equilibrium adsorption capacity of adsorbents and equilibrium concentrations of metal ions at certain solution concentration, respectively.

Table S1. Thermodynamic parameters for Pb(II) adsorption on CCNC-nZVI.

Ion concentration /mg·L ⁻¹	ΔH /kJ·mol ⁻¹	ΔS /kJ·K ⁻¹ ·mol ⁻¹	ΔG /kJ·mol ⁻¹		
			298.15 K	308.15 K	318.15 K
50	-220.93	-0.66	-21.11	-21.82	-7.87
100	-58.75	-0.16	-10.39	-8.95	-7.15
